

# BALL MILL 5

## TROUBLESHOOTING GUIDE

Fictional Industrial Equipment Documentation — Prototype Demonstration

|               |                           |
|---------------|---------------------------|
| Document No.  | BM05-TG-001               |
| Equipment Tag | BM-05                     |
| Equipment     | Ball Mill 5               |
| Model         | FPM-BM5200-2C (Fictional) |
| Application   | Cement Grinding           |
| Revision      | Rev. 01                   |
| Issue Date    | 01 September 2026         |
| Status        | SAMPLE / NON-OPERATIONAL  |

**IMPORTANT:** This guide is entirely fictional and is intended only for demonstrating a digital maintenance-documentation system. The fault codes, alarm limits, diagnostic steps and corrective actions must not be applied to real equipment without approved manufacturer and site procedures.

# 1. TROUBLESHOOTING PHILOSOPHY AND SAFETY

## 1.1 Purpose

This guide provides a structured fictional method for identifying common operating and maintenance symptoms associated with BM-05. It is organized around symptoms, possible causes, diagnostic checks and corrective actions.

## 1.2 Troubleshooting Principles

- Start with the simplest and safest possible explanation.
- Confirm the symptom using an actual reading, alarm or physical observation.
- Use trends and historical data when available.
- Do not bypass protective devices to restore production.
- Separate process problems from mechanical, electrical and instrumentation faults.
- Correct the root cause where possible rather than repeatedly resetting the same alarm.

## 1.3 Safety Requirements

**WARNING:** Troubleshooting around a ball mill may expose personnel to rotating equipment, high-voltage electrical systems, hot surfaces, stored energy, heavy components and process material. Any inspection requiring access to hazardous areas must follow the approved isolation and permit system.

## 1.4 Diagnostic Priority

| Priority | Action                                                                  |
|----------|-------------------------------------------------------------------------|
| 1        | Protect people and equipment; stop if the condition is hazardous.       |
| 2        | Record alarm, trip, time and operating conditions.                      |
| 3        | Check recent changes in feed, load, lubrication or auxiliary equipment. |
| 4        | Compare measurements with normal baseline trends.                       |
| 5        | Inspect the relevant system using approved methods.                     |
| 6        | Repair, test and document the outcome.                                  |

## 2. ALARM AND TRIP CODE DIRECTORY

### 2.1 Main Protection Codes

| Code     | Alarm / Trip                                  | Severity   | Initial Response                                      |
|----------|-----------------------------------------------|------------|-------------------------------------------------------|
| BM05-T01 | Low lubrication pressure                      | Trip       | Protect drive; investigate lubrication circuit.       |
| BM05-T02 | Main bearing high temperature                 | Trip       | Stop/controlled shutdown and investigate.             |
| BM05-T03 | High mill vibration                           | Trip       | Stop if required; inspect mechanical condition.       |
| BM05-T04 | Main motor overload                           | Trip       | Investigate load and electrical protection.           |
| BM05-T05 | Emergency stop active                         | Trip       | Do not reset until cause is confirmed safe.           |
| BM05-T06 | Gearbox oil high temperature                  | Alarm/Trip | Check oil flow, cooling and load.                     |
| BM05-T07 | Lubrication filter differential pressure high | Alarm      | Inspect filter condition.                             |
| BM05-T08 | Motor bearing temperature high                | Alarm/Trip | Investigate lubrication/cooling/mechanical condition. |
| BM05-T09 | Downstream equipment unavailable              | Permissive | Restore downstream readiness before starting.         |
| BM05-T10 | Mill start permissive not satisfied           | Permissive | Identify open permissive in control system.           |

### 2.2 Alarm Handling

An alarm is an indication requiring attention; it is not automatically proof of a failed component. Verify the process value and sensor plausibility before replacing hardware.

### 2.3 Repeated Trips

Repeated trips should be treated as a fault condition. Record the sequence of events and investigate the initiating cause. Do not defeat or permanently bypass protection.

## 3. MILL WILL NOT START

### 3.1 Diagnostic Flow

| Check            | Possible Cause        | Diagnostic Action                                | Corrective Direction                 |
|------------------|-----------------------|--------------------------------------------------|--------------------------------------|
| Emergency stop   | E-stop active         | Verify status at approved HMI/panel              | Clear cause; reset under procedure.  |
| Lubrication      | No oil pressure       | Check pump status, level and pressure indication | Restore lubrication system.          |
| Downstream       | Equipment unavailable | Check downstream permissive                      | Restore required readiness.          |
| Motor protection | Trip active           | Review protection indication                     | Authorized electrical investigation. |
| PLC permissive   | Open permissive       | Identify first open condition                    | Correct initiating condition.        |
| Local/remote     | Wrong control mode    | Check selected control station                   | Select approved operating mode.      |
| Instrumentation  | Invalid signal        | Compare indication with field condition          | Inspect sensor/wiring.               |

### 3.2 Mill Starts Then Stops

| Symptom                  | Likely Area                 | Checks                                              |
|--------------------------|-----------------------------|-----------------------------------------------------|
| Stops immediately        | Start permissive/protection | Review trip history and interlock sequence.         |
| Stops after acceleration | Motor/load/mechanical       | Review current, vibration and bearing values.       |
| Stops after feed starts  | Process/feed                | Check feed rate, material condition and motor load. |
| Stops intermittently     | Instrumentation/control     | Review event timestamps and signal stability.       |

### 3.3 Recommended Record

Record start command time, motor current, lubrication pressure, bearing temperatures, active alarms, trip code, mill status and process feed condition.

## 4. HIGH VIBRATION

### 4.1 Symptom Assessment

High vibration should be investigated using trend data and measurements at consistent locations. Compare the current value with the established baseline rather than relying only on a single reading.

| Possible Cause           | Typical Indication                        | Diagnostic Check                                               |
|--------------------------|-------------------------------------------|----------------------------------------------------------------|
| Mechanical looseness     | Increasing vibration with unusual noise   | Inspect accessible fasteners/foundation under safe conditions. |
| Misalignment             | Vibration associated with drive condition | Review alignment records and coupling condition.               |
| Bearing deterioration    | Temperature and vibration trend increase  | Analyze vibration pattern and bearing temperature.             |
| Liner/internal condition | Abnormal mill sound/vibration             | Investigate during planned shutdown.                           |
| Unbalanced condition     | Speed-related vibration                   | Review spectrum/trend where available.                         |
| Gearbox condition        | Gear mesh-related vibration/noise         | Review gearbox vibration and oil condition.                    |

### 4.2 Corrective Strategy

- Verify the measurement instrument and sensor condition.
- Check whether vibration changed after maintenance, liner work or alignment work.
- Compare drive-end and non-drive-end measurements.
- Review gearbox and bearing temperature trends.
- Escalate significant or rapidly increasing vibration to engineering/maintenance.

### 4.3 Do Not

Do not continue operation solely because the vibration alarm can be reset. Do not enter the mill or remove guards while rotating equipment remains hazardous.

## 5. HIGH BEARING TEMPERATURE

| Observation                     | Potential Cause                       | Diagnostic Approach                                      |
|---------------------------------|---------------------------------------|----------------------------------------------------------|
| Both bearings rising            | High load / oil temperature / cooling | Review load, oil supply temperature and cooling.         |
| One bearing rising              | Local lubrication or bearing issue    | Compare oil flow and vibration; inspect local condition. |
| Temperature rises after startup | Lubrication/circulation issue         | Confirm oil flow and pressure.                           |
| Temperature fluctuates          | Sensor or intermittent flow           | Compare redundant/independent readings.                  |
| Temperature rises with load     | Process overload                      | Review feed and motor current.                           |

### 5.1 Fictional Reference Values

| Condition                       | Fictional Value |
|---------------------------------|-----------------|
| Normal main bearing temperature | 35–65 °C        |
| High alarm                      | 70 °C           |
| Trip                            | 80 °C           |

### 5.2 Investigation Sequence

- Confirm the displayed temperature with an approved independent measurement where practical.
- Check lubrication pressure, flow and oil supply temperature.
- Inspect for leakage or restriction.
- Review vibration trend.
- Review recent maintenance and operating changes.
- If the temperature continues to rise, stop or reduce operation according to the approved protection philosophy and investigate.

### 5.3 Common Incorrect Diagnosis

A high temperature indication should not automatically be interpreted as a failed bearing. Sensor faults, poor lubrication, excessive load, cooling problems and mechanical misalignment can produce similar symptoms.

## 6. LUBRICATION AND GEARBOX PROBLEMS

### 6.1 Low Lubrication Pressure

| Check           | Possible Finding           | Action                                                               |
|-----------------|----------------------------|----------------------------------------------------------------------|
| Reservoir level | Low oil level              | Investigate loss/leakage and restore level using approved lubricant. |
| Pump            | Pump not running           | Check electrical/control status by authorized personnel.             |
| Filter          | High differential pressure | Inspect filter and contamination.                                    |
| Piping          | Restriction/leakage        | Inspect under approved isolation.                                    |
| Pressure sensor | Implausible reading        | Verify indication and instrument condition.                          |

### 6.2 High Gearbox Oil Temperature

| Possible Cause             | Diagnostic Check                             |
|----------------------------|----------------------------------------------|
| Low oil level              | Verify level and leakage.                    |
| Cooling problem            | Check cooler performance and cooling medium. |
| High mechanical load       | Review motor current and process conditions. |
| Oil degradation            | Review oil analysis and service history.     |
| Gearbox mechanical problem | Review vibration, noise and oil debris.      |

### 6.3 Abnormal Gearbox Noise

Document when the noise occurs, whether it changes with load, and whether it is accompanied by vibration or temperature changes. Review gearbox vibration data and oil condition before deciding on component replacement.

### 6.4 Lubrication Contamination

Water, particles or abnormal wear debris may indicate contamination or component deterioration. Take an approved oil sample and use trend analysis or laboratory results where available.

## 7. MOTOR, DRIVE AND PROCESS SYMPTOMS

### 7.1 Main Motor Overload

| Possible Cause        | Checks                                   | Corrective Direction                      |
|-----------------------|------------------------------------------|-------------------------------------------|
| Excessive feed        | Review feed rate and process trend       | Restore approved operating range.         |
| Material buildup      | Review process condition                 | Inspect during safe planned intervention. |
| Mechanical resistance | Review vibration, noise and temperatures | Mechanical investigation.                 |
| Electrical fault      | Review protection and current balance    | Authorized electrical testing.            |
| Starting issue        | Review acceleration/current history      | Investigate motor/drive system.           |

### 7.2 Motor Does Not Reach Normal Speed

Check motor protection status, starting sequence, drive configuration where applicable, current behavior and mechanical load. Electrical diagnosis must be performed by authorized personnel using approved procedures.

### 7.3 Excessive Power Consumption

- Compare current feed rate with normal production conditions.
- Check material characteristics and mill loading.
- Review mill ventilation/process conditions where applicable.
- Inspect for abnormal mechanical resistance.
- Compare current and power trends with historical baseline.

### 7.4 Reduced Grinding Performance

Investigate feed characteristics, mill loading, grinding-media condition, liner condition, diaphragm condition, ventilation and process settings. Mechanical inspection should be planned rather than performed under unsafe operating conditions.

## 8. INSTRUMENTATION, CONTROL AND INTERMITTENT FAULTS

### 8.1 Implausible Sensor Reading

| Symptom                 | Potential Cause               | Check                                              |
|-------------------------|-------------------------------|----------------------------------------------------|
| Sudden temperature jump | Sensor/wiring issue           | Compare with trend and independent measurement.    |
| Pressure remains fixed  | Sensor or signal fault        | Compare with physical gauge/system behavior.       |
| Vibration signal lost   | Sensor/cable issue            | Check diagnostic status and connections when safe. |
| Unstable reading        | Loose connection/interference | Review signal quality and wiring.                  |

### 8.2 Intermittent Trips

Intermittent faults are often difficult to diagnose because the equipment may appear normal after a reset. Capture the exact timestamp, active alarms, process conditions, sensor values and preceding maintenance activity.

| Investigation Item  | Record |
|---------------------|--------|
| Date/time           | _____  |
| Trip code           | _____  |
| Motor load          | _____  |
| Oil pressure/temp.  | _____  |
| Bearing temperature | _____  |
| Vibration           | _____  |
| Feed condition      | _____  |
| Recent maintenance  | _____  |

### 8.3 Control-System Checks

Review the alarm/event sequence and identify the first abnormal signal rather than the final trip generated by the control system. A downstream trip may be a consequence rather than the root cause.

### 8.4 Instrument Replacement

Replace sensors only after reasonable verification that the sensor or signal path is responsible. Record the removed component, replacement part, calibration status and post-replacement reading.

## 9. FAULT DIAGNOSIS RECORD AND QUICK REFERENCE

### 9.1 Fault Investigation Form

| Field                      | Entry               |
|----------------------------|---------------------|
| Equipment                  | Ball Mill 5 / BM-05 |
| Date & time                | _____               |
| Reported symptom           | _____               |
| Alarm / trip code          | _____               |
| Operating load             | _____               |
| Bearing temperature        | _____               |
| Oil pressure / temperature | _____               |
| Vibration                  | _____               |
| Initial suspected cause    | _____               |
| Inspection findings        | _____               |
| Root cause                 | _____               |
| Corrective action          | _____               |
| Post-repair test           | _____               |
| Technician / supervisor    | _____               |

### 9.2 Quick Diagnostic Matrix

| Symptom                  | First Areas to Check                                                                |
|--------------------------|-------------------------------------------------------------------------------------|
| Won't start              | Emergency stop, lubrication, permissives, motor protection, downstream readiness.   |
| High vibration           | Measurement validity, bearings, alignment, gearbox, foundation, internal condition. |
| High bearing temperature | Lubrication, cooling, load, vibration, sensor validity.                             |
| Low oil pressure         | Oil level, pump, filter, restriction, leakage, pressure signal.                     |
| Gearbox overheating      | Oil level, cooling, load, oil condition, vibration.                                 |
| Motor overload           | Feed/load, mechanical resistance, electrical protection.                            |
| Repeated trip            | Event history, first abnormal signal, recent changes, instrumentation.              |

### 9.3 Escalation Criteria

Escalate when a fault involves repeated protective trips, rapidly increasing temperature or vibration, suspected structural damage, abnormal gearbox condition, electrical protection faults, fire, uncontrolled material release or any condition beyond the technician's approved authority.

**FINAL DISCLAIMER:** All codes, values, diagnoses and procedures in this ten-page guide are fictional. Use only approved manufacturer documentation, site procedures, risk assessments and competent engineering judgement when working on real equipment.

**END OF DOCUMENT — BM05-TG-001 Rev. 01**
